

Perytons^{TMTM} Monitoring for SOA (Service Oriented Architecture)

The Peryton-Monitoring Add-On allows to locally or remotely monitor operational networks for performance and potential failures.

Each of the remotely spread analyzers capturing live data, and using the Open Source Rules (user defined), can generate statistics charts and events summarizing the performance and possible failures found in the specific local network being monitored.

The information from the different analyzers is polled by the PerytonsTM SOA server (can be developed by the user, or can be a PerytonsTM server) via dedicated Application Programming Interfaces (APIs). The results are available to authorized personal accessing the SOA server via a simple web browser.
